e not long enough to trip most breakers which are designed to heat up slowly before going open.
Most SR engineers are familiar with current starved amp problems, but I have

A dedicated line from the main panel (home run) is the best approach. Most

for 30 amps at peaks. This is also enough to risk electrical fires if you are running off a normal residential 15-Amp line that is shared with other devices.

A dedicated AC run should also help minimize ground loop issues in a well-designed balanced audio studio.

At least you know that this is just WINE :-)

For those who don't know, it's a windows API emulator, and outside of the list of tested, "approved" applications it doesn't run much else (of any complexity) reliably. Since it's an emulator it's definitely not for multitrack audio apps :-)

One thing you said caught my eye:

"gene Lennon" <glennon@NOSPmyrealbox.com> wrote:

>Most

>for 30 amps at peaks.

Actually, amps use far less current than this, which is why you see poorly engineered sound systems, with 8 amplifiers all running off one 15-amp circuit.

The QSC website has a page where you can download a document listing the current draw of all their amps.
